INSTABILITY OF TURING TYPE FOR A REACTION-DIFFUSION SYSTEM WITH UNILATERAL OBSTACLES MODELED BY VARIATIONAL INEQUALITIES

MARTIN VÄTH, Berlin

(Received September 20, 2013)

Abstract. We consider a reaction-diffusion system of activator-inhibitor type which is subject to Turing’s diffusion-driven instability. It is shown that unilateral obstacles of various type for the inhibitor, modeled by variational inequalities, lead to instability of the trivial solution in a parameter domain where it would be stable otherwise. The result is based on a previous joint work with I.-S.Kim, but a refinement of the underlying theoretical tool is developed. Moreover, a different regime of parameters is considered for which instability is shown also when there are simultaneously obstacles for the activator and inhibitor, obstacles of opposite direction for the inhibitor, or in the presence of Dirichlet conditions.

Keywords: reaction-diffusion system; Signorini condition; unilateral obstacle; instability; asymptotic stability; parabolic obstacle equation

1. Introduction

Let $\Omega \subseteq \mathbb{R}^N$ be a bounded domain with a Lipschitz boundary, and $\Gamma_D \subseteq \partial \Omega$. Given $f_1, f_2 : \mathbb{R}^2 \to \mathbb{R}$, we consider the reaction-diffusion system

\begin{align}
    u_t &= d_1 \Delta u + f_1(u, v) \\
    v_t &= d_2 \Delta v + f_2(u, v)
\end{align}

with diffusion coefficients $d_1, d_2 > 0$ and Neumann-Dirichlet boundary conditions

\begin{align}
    \begin{cases}
    u = v = 0 & \text{on } \Gamma_D, \\
    \frac{\partial u}{\partial n} = \frac{\partial v}{\partial n} = 0 & \text{on } \partial \Omega \setminus \Gamma_D.
    \end{cases}
\end{align}

The results were obtained in the Framework of the SFB 647 of the DFG. Financial support by the DFG is gratefully acknowledged.
We will supplement (1.1), (1.2) with unilateral obstacle conditions and show that these obstacles will change the stability for certain diffusion coefficients \((d_1, d_2)\). The result is based on a refinement of a theoretical tool developed in [4]. In a sense, the result presented in this paper complements the application from [4], since we consider a different range of values \((d_1, d_2)\) than in [4], which leads to a result under somewhat different assumptions on the obstacle/boundary conditions (and allows us also to treat \(\Gamma_D \neq \emptyset\)).

2. Auxiliary and main results

We assume that \(f_i(0,0) = 0\) with \(f_i\) being differentiable at \((0,0)\), and we are interested in the stability of the trivial solution \(u = v = 0\) of (1.1), (1.2). We suppose that system (1.1) is subject to Turing’s diffusion-driven instability [7], that is, we assume that without diffusion \((d_1 = d_2 = 0)\) the solution \(u = v = 0\) is linearly stable. In other words, we assume that the Jacobi-matrix \((b_{ij})\) of \((f_1, f_2)\) at \((0,0)\) has its spectrum in the left half-plane. For definiteness, and to avoid a certain Hopf-type instability later on, we assume \(b_{11} > 0\). It follows from Vieta’s theorem that these assumptions are equivalent to the sign conditions

\[
(2.1) \quad b_{11} > 0 > b_{22}, \quad b_{12}b_{21} < 0, \quad b_{11} + b_{22} < 0, \quad b_{11}b_{22} - b_{12}b_{21} > 0.
\]

We rewrite (1.1) in the form

\[
(2.2) \quad u_t = d_1 \Delta u + b_{11} u + b_{12} v + g_1(u,v), \\
v_t = d_2 \Delta v + b_{21} u + b_{22} v + g_2(u,v),
\]

where

\[
(2.3) \quad \lim_{(u,v) \to (0,0)} \frac{g_i(u,v)}{|u| + |v|} = 0 \quad \text{for } i = 1, 2.
\]

We assume that \(f_i\) (and thus \(g_i\)) satisfy the Lipschitz type condition

\[
(2.4) \quad |f_i(u_1, v_1) - f_i(u_2, v_2)| \leq C(1 + |u_1| + |u_2| + |v_1| + |v_2|)^{\alpha_N}(|u_1 - u_2| + |v_1 - v_2|)
\]

for all \(u_j, v_j \in \mathbb{R}\), where \(C \in [0, \infty)\) and \(\alpha_N := 2/(N - 2)\) if \(N > 2\) or \(0 < \alpha_N < \infty\) if \(N = 2\). In case of space dimension \(N = 1\), we assume instead of (2.4) only that \(f_i\) satisfy a local Lipschitz condition in some neighborhood of \((u, v) = (0,0)\).

It is well-known (see [6] for \(N = 1\) or [1] for the general case) that \((0,0)\) is linearly stable if and only if \((d_1, d_2) \in \mathbb{R}_+^2\) lies in the open set \(D_S\) to the right/under each of
the countably many hyperbolas

\[ C_n = \left\{ (d_1, d_2) \in \mathbb{R}_+^2 : (\kappa_n d_1 - b_{11})(\kappa_n d_2 - b_{22}) = b_{12}b_{21} \right\} \]

\[ = \left\{ (d_1, d_2) \in \mathbb{R}_+^2 : d_2 = \frac{b_{12}b_{21}/\kappa_n^2 + b_{22}}{d_1 - b_{11}/\kappa_n} \right\} , \]

see Figure 1. Here, \( 0 < \kappa_1 < \kappa_2 < \ldots \to \infty \) denote the strictly positive eigenvalues of \(-\Delta\) with Dirichlet-Neumann boundary condition (1.2) (in case \( \Gamma_D = \emptyset \) the trivial eigenvalue \( \kappa_0 = 0 \) is omitted from the sequence).

![Figure 1. Hyperbolas (2.5) determining \( D_S \).](image)

Although the above mentioned result is mathematical folklore, we will give a new simple proof of this observation based on spectral calculus in Section 5. In order to compare this observation with our subsequent main result concerning obstacles, we formulate now precisely what the linear stability implies in the terminology of dynamical systems.

To this end, we consider the weak form of (1.1), (1.2), that is, we consider the Hilbert space

\[ \mathbb{V} := \{ u \in W^{1,2}(\Omega) : u|_{\Gamma_D} = 0 \} \]

(here and in the following, restrictions \( u|_{\Gamma_D} \) are understood in the sense of traces, of course), and then understand the solutions of (1.1), (1.2) as absolutely continuous functions \( u, v : I \to L^2(\Omega) \) (\( I \) denoting some interval) satisfying the variational equations

\[ u \in \mathbb{V} , \quad \int_{\Omega} (u' - f_1(u,v))\varphi \, dx + d_1 \int_{\Omega} \nabla u \nabla \varphi \, dx = 0 \quad \text{for all } \varphi \in \mathbb{V} , \]

\[ v \in \mathbb{V} , \quad \int_{\Omega} (v' - f_2(u,v))\psi \, dx + d_2 \int_{\Omega} \nabla v \nabla \psi \, dx = 0 \quad \text{for all } \psi \in \mathbb{V} . \]
Note that, since $u$ and $v$ are absolutely continuous and $L^2(\Omega)$ is separable and reflexive, the derivatives $u'$ and $v'$ exist almost everywhere, and the corresponding fundamental theorem of calculus holds with the Lebesgue-Bochner integral, and so it follows from e.g. [8], Theorem 4.4.4, that the partial derivatives of $u(t,s) = u(t)(s)$ with respect to $t$ exist for almost all $(t,s)$ and satisfy $u_t(t,s) = u'(t)(s)$ for almost all $(t,s)$.

We call the trivial solution $u = v = 0$ of system (2.6) \textit{asymptotically stable} in the $\mathbb{V}^2$ topology if each neighborhood $U \subseteq \mathbb{V}^2$ of $(0,0)$ contains a neighborhood $V \subseteq \mathbb{V}^2$ of $(0,0)$ such that all solutions $(u,v)$ of (2.11) with $(u(0),v(0)) \in V$ satisfy $(u(t),v(t)) \in U$ for all $t > 0$ and $u(t) \to 0$ and $v(t) \to 0$ as $t \to \infty$ in the topology of $\mathbb{V}$.

\textbf{Proposition 1.} Assume (2.1), (2.3), and (2.4). Then for $(d_1,d_2) \in D_S$ the trivial solution $u = v = 0$ of system (2.6) is asymptotically stable in the $\mathbb{V}^2$ topology, the convergence $u(t),v(t) \to 0$ as $t \to \infty$ being exponentially fast.

The associated linearization has its spectrum in the left half-plane, the real part of the spectral values being even uniformly bounded by a negative number.

\textbf{Proof.} See Section 5. \hfill \Box

Our aim in this paper is to show that the (asymptotic) stability of $(0,0)$ in (1.1), (1.2) is lost even for certain $(d_1,d_2) \in D_S$ if on some (nontrivial) parts of $\overline{\Omega} \setminus \Gamma_D$ appropriate unilateral conditions are prescribed.

More precisely, we fix measurable (with respect to Lebesgue measure) subsets $\Omega^\pm_i \subseteq \Omega$ and measurable (with respect to Hausdorff measure of dimension $N-1$) sets $\Gamma^\pm_i \subseteq \Gamma := \partial \Omega \setminus \Gamma_D$ such that

\begin{equation}
(\Omega^+_i \cup \Gamma^+_i) \cap (\Omega^-_i \cup \Gamma^-_i) = \emptyset \quad (i = 1,2).
\end{equation}

In physical terms, these eight sets are the locations in the interior or on the boundary of $\Omega$ where we will describe a certain regulating system or unilateral membrane which provides some unilateral flow in or out for $u$ or $v$, respectively. Condition (2.7) means that the locations for opposite flux should not touch each other. In applications, most of these eight sets are empty, that is, not all possible sorts of obstacles are described simultaneously in the same problem (and we need not have flux in- and outside simultaneously). However, we will \textit{not exclude} the possibility that they are all nonempty and thus write a complete system which can contain all possible cases simultaneously.

In order to simplify notation, we set

$\Omega_i := \Omega^+_i \cup \Omega^-_i$, \hspace{1em} $\Gamma_i := \Gamma^+_i \cup \Gamma^-_i$ \hspace{1em} ($i = 1,2$).
We will require that there is at least some obstacle for the inhibitor \( v \), that is:

\[
\text{(2.8)} \quad \mes_N \Omega_2 > 0 \quad \text{or} \quad \mes_N \Gamma_2 > 0 \quad \text{(or both)}.
\]

Actually, we will allow that \( \Omega_i \) and \( \Gamma_i \) consist of subregions where we will describe “integral” obstacles (in the remaining regions, “pointwise” obstacles will be described).

To fix the locations of these “integral” obstacles, we assume that finitely many measurable subsets \( \Omega^\pm_{i,j} \subseteq \Omega^\pm_i \) (\( j \in J^\pm_{1,i} \)) and \( \Gamma^\pm_{i,j} \subseteq \Gamma^\pm_i \) (\( j \in J^\pm_{2,i} \)) are given such that

\[
\Omega^\pm_{i,j} \cap \Omega^\pm_{i,k} = \emptyset \quad \text{for all} \ j, k \in J^\pm_{1,i}, \ j \neq k,
\]

and

\[
\Gamma^\pm_{i,j} \cap \Gamma^\pm_{i,k} = \emptyset \quad \text{for all} \ j, k \in J^\pm_{2,i}, \ j \neq k,
\]

and we define the remainder regions (where we will describe “pointwise” obstacles) as

\[
\hat{\Omega}^\pm_i := \Omega^\pm_i \setminus \bigcup_{j \in J^\pm_{1,i}} \Omega^\pm_{i,j} \quad \text{and} \quad \hat{\Gamma}^\pm_i := \Gamma^\pm_i \setminus \bigcup_{j \in J^\pm_{2,i}} \Gamma^\pm_{i,j}.
\]

It is explicitly admissible that some (or all) of the finite index sets \( J^\pm_{1,i}, J^\pm_{2,i} \) \((i = 1, 2)\) are empty, that is, we do not require integral obstacles but we do not exclude their presence. Similarly, also the remainder regions \( \hat{\Omega}^\pm_i \) or \( \hat{\Gamma}^\pm_i \) are allowed to be empty.

Now our general unilateral problem can be formulated as follows:

\[
\text{(2.9)} \quad u_t = d_1 \Delta u + f_1(u,v) \quad \text{on} \ \Omega \setminus \Omega_1,
\]

\[
\pm u_t \mp (d_1 \Delta u + f_1(u,v)) \geq 0, \quad \pm u \geq 0 \quad \text{on} \ \hat{\Omega}^\pm_1,
\]

\[
(-u_t + d_1 \Delta u + f_1(u,v))u = 0 \quad \text{on} \ \hat{\Omega}^\pm_1,
\]

\[
\pm u_t \mp (d_1 \Delta u + f_1(u,v)) = \text{const} \geq 0, \quad \pm \int_{\Omega^\pm_{1,j}} u \, dx \geq 0 \quad \text{on} \ \Omega^\pm_{1,j},
\]

\[
(-u_t + d_1 \Delta u + f_1(u,v)) \int_{\Omega^\pm_{1,j}} u \, dx = 0 \quad \text{on} \ \Omega^\pm_{1,j},
\]

\[
v_t = d_2 \Delta v + f_2(u,v) \quad \text{on} \ \Omega \setminus \Omega_2,
\]

\[
\pm v_t \mp (d_2 \Delta v + f_2(u,v)) \geq 0, \quad \pm v \geq 0 \quad \text{on} \ \hat{\Omega}^\pm_2,
\]

\[
(-v_t + d_2 \Delta v + f_2(u,v))v = 0 \quad \text{on} \ \hat{\Omega}^\pm_2,
\]

\[
\pm v_t \mp (d_2 \Delta v + f_2(u,v)) = \text{const} \geq 0, \quad \pm \int_{\Omega^\pm_{1,j}} v \, dx \geq 0 \quad \text{on} \ \Omega^\pm_{1,j},
\]

\[
(-v_t + d_2 \Delta v + f_2(u,v)) \int_{\Omega^\pm_{1,j}} v \, dx = 0 \quad \text{on} \ \Omega^\pm_{1,j},
\]
with Dirichlet/Neumann/Signorini/integral-Signorini type boundary conditions:

\[
\begin{align*}
(2.10) \quad & u = v = 0 \quad \text{on } \Gamma_D, \\
& \frac{\partial u}{\partial n} = 0 \quad \text{on } \Gamma \setminus \Gamma_1, \\
& \pm \frac{\partial u}{\partial n} \geq 0, \quad \pm u \geq 0, \quad \frac{\partial u}{\partial n} u = 0 \quad \text{on } \hat{\Gamma}^+_1, \\
& \pm \frac{\partial u}{\partial n} = \text{const} \geq 0, \quad \pm \int_{\Gamma^+_1,j} u \, dx \geq 0, \quad \frac{\partial u}{\partial n} \int_{\Gamma^+_1,j} u \, dx = 0 \quad \text{on } \Gamma^+_{1,j}, \\
& \frac{\partial v}{\partial n} = 0 \quad \text{on } \Gamma \setminus \Gamma_2, \\
& \pm \frac{\partial v}{\partial n} \geq 0, \quad \pm v \geq 0, \quad \frac{\partial v}{\partial n} v = 0 \quad \text{on } \hat{\Gamma}^+_2, \\
& \pm \frac{\partial v}{\partial n} = \text{const} \geq 0, \quad \pm \int_{\Gamma^+_2,j} v \, dx \geq 0, \quad \frac{\partial v}{\partial n} \int_{\Gamma^+_2,j} v \, dx = 0 \quad \text{on } \Gamma^+_{2,j}.
\end{align*}
\]

Here, the shortcuts \( \pm \) and \( \mp \) are understood such that in each line either the upper or lower sign is chosen simultaneously. Roughly speaking, the unilateral conditions mean the following: At each obstacle point (or integral region) “normally” the original system (1.1)/(1.2) is satisfied unless \( u \) or \( v \) lies under/over the threshold 0. In the latter case, the obstacle (e.g. a unilateral membrane) becomes active, forcing \( u \) or \( v \) to be 0 by activating a corresponding source/sink. On each integral part, the “measurement” of the membrane is only “in the mean”, and the activated source/sink is uniform (that is, constant on the whole integral part).

Actually, we will consider only the weak form of (2.9), (2.10) which is much easier to formulate: We consider the following two cones of obstacles for \( u \) (\( i = 1 \)) or \( v \) (\( i = 2 \)), respectively:

\[
K_i := \left\{ u \in V : \pm u|_{\tilde{\Omega}^i} \geq 0 \quad \text{and} \quad \pm \int_{\tilde{\Omega}^i,j} u \, dx \geq 0 \quad \text{for all } j \in J^\pm_{1,i}, \right. \\
\quad \left. \text{and} \quad \pm u|_{\tilde{\Gamma}^i} \geq 0 \quad \text{and} \quad \pm \int_{\tilde{\Gamma}^i,j} u \, dx \geq 0 \quad \text{for all } j \in J^\pm_{2,i} \right\}.
\]

Then the weak form of (2.9), (2.10) becomes

\[
(2.11) \quad \begin{align*}
u \in K_1, \quad & \int_{\Omega} (u' - f_1(u,v))(\varphi - u) \, dx + d_1 \int_{\Omega} \nabla u(\nabla \varphi - \nabla u) \, dx \geq 0 \\
& \quad \text{for all } \varphi \in K_1, \\
\nu \in K_2, \quad & \int_{\Omega} (v' - f_2(u,v))(\psi - v) \, dx + d_2 \int_{\Omega} \nabla v(\nabla \psi - \nabla v) \, dx \geq 0 \\
& \quad \text{for all } \psi \in K_2.
\end{align*}
\]
In order to formulate our main result, we have to consider the eigenspaces $E_n$ of $-\Delta$ (with (1.2)) to the eigenvalues $\kappa_n$, that is,

$$E_n := \left\{ u \in \mathbb{V}: \int_{\Omega} \nabla u \nabla \varphi \, dx = \kappa_n \int_{\Omega} u \varphi \, dx \text{ for all } \varphi \in \mathbb{V} \right\}.$$ 

Moreover, we define the sets

$$K_i^\circ := \left\{ u \in \mathbb{V}: \text{ess inf}_{\overline{\Omega}_i^\pm} (\pm u) > 0 \text{ and } \pm \int_{\Omega_i^\pm} u \, dx > 0 \text{ for all } j \in J_{i,i}^\pm \right\},$$

which in a certain sense might be considered as an “interior” of $K_i$. (However, $K_i^\circ$ is not the interior of $K_i$ in the topological sense for $N > 1$, since the latter is empty in case $N > 1$.)

Remark 1. For the case when $\partial \Omega$, $\Gamma_D$, and $\hat{\Gamma}_i^\pm$ are smooth manifolds with a smooth boundary, we can relax the definition of $K_i^\circ$ by replacing the requirement $\text{ess inf}_{\overline{\Omega}_i^\pm} (\pm u) > 0$ by the weaker requirement that $\pm u|_{\overline{\Gamma}_i^\pm} > 0$ almost everywhere.

Let $d_0 = (d_{1,0}, d_{2,0}) \in \mathbb{R}_+^2 \cap \partial \mathcal{D}_S$, that is, $d_0$ lies either on a single hyperbola $C_n \setminus \bigcup_{m \neq n} C_m$, or $d_0$ is the intersection point of exactly two hyperbolas $C_n \cap C_m$ ($n \neq m$). In the former case, we put $\sigma := \text{sgn} b_{12}$ and require

$$E_n \cap K_2^\circ \cap \sigma K_1^\circ \neq \emptyset \quad \text{and} \quad E_n \cap K_2 \cap (-\sigma K_1) \subseteq \sigma K_1,$$

and in the latter case, we put for $i = n, m$

$$\alpha_i(d_0) := \frac{-b_{12}}{b_{11} - d_{1,0} \kappa_i} = \frac{d_{2,0} \kappa_i - b_{22}}{b_{21}},$$
$$\alpha_i^*(d_0) := \frac{d_{2,0}^1(-b_{21})}{d_{1,0}^1 b_{11} - \kappa_i} = \frac{\kappa_i - d_{2,0}^{-1} b_{22}}{d_{1,0}^{-1} b_{12}},$$

and require the following:

$$\text{There are } e_i \in E_i \ (i = n, m)$$

with $e_n + e_m \in K_2^\circ$, $\alpha_i^*(d_0) e_n + \alpha_m^*(d_0) \in K_1^\circ$.

For every $e_i \in E_i \ (i = n, m)$ there holds

$$(e_n + e_m \in K_2 \text{ and } \alpha_n(d)e_n + \alpha_m(d)e_m \in K_1)$$

$$\implies \alpha_n^*(d)e_n + \alpha_m^*(d)e_m \in K_1.$$
Noting that $\text{sgn} \alpha_i(d_0) = \sigma = -\text{sgn} \alpha_i^*(d_0)$, we have actually a consistency of the requirements for the two cases: The first hypothesis of (2.13) is weaker than the first hypothesis from (2.12) while the second hypothesis is stricter.

Since these hypotheses are rather technical, let us first discuss them: First of all, the requirements $K_i^0 \neq \emptyset$ imply that the regions of “pointwise” obstacles should be strictly separated from $\Gamma_D$. Hence, the following condition is necessary for (2.12) or (2.13):

(2.14) \[ \overline{\Gamma}_i^+ \cap \overline{\Gamma}_D = \emptyset \quad \text{and} \quad \overline{\Omega}_i^+ \cap \overline{\Gamma}_D = \emptyset \quad \text{for} \ i = 1, 2. \]

Remark 2. In the setting of Remark 1, we can relax the first condition in (2.14) slightly by allowing the boundary manifolds of $\overline{\Gamma}_i^\pm$ and $\Gamma_D$ to intersect.

The second hypothesis in (2.12) and (2.13) restricts the possible obstacles for $u$: If we have no obstacles for $u$ ($K_1 = \emptyset$), then the second hypothesis in (2.12) and (2.13) is automatically satisfied. However, the less obstacles we have for $v$, the more restrictions are imposed by this hypothesis on our choice of obstacles for $u$. In the extreme case, if there were no obstacle for $v$ ($K_2 = \emptyset$), then the second condition would imply that $K_1$ is a linear subspace and thus would not allow any reasonable obstacle for $u$: This is the reason why our whole discussion only makes sense under hypothesis (2.8).

In some important situations, the necessary requirements (2.14) are already sufficient for (2.12)/(2.13): Recall that if we have a Dirichlet condition, that is, if

(2.15) \[ \Gamma_D \text{ has positive } (N-1)-\text{dimensional Hausdorff measure,} \]

then the first eigenspace $E_1$ is one-dimensional and generated by a strictly positive function. Thus, under hypothesis (2.14) and (2.15) one can usually apply the following result at least with $n = 1$:

**Proposition 2.** Suppose (2.1). Assume that the obstacles for $u$ and $v$ act only into the same (if $b_{12} > 0$) or opposite (if $b_{12} < 0$) direction, that is, we assume that one of the following four cases holds:

(2.16) \[
\begin{align*}
b_{12} > 0 \quad &\text{and} \quad \Gamma_1^+ = \Omega_1^+ = \Gamma_2^+ = \Omega_2^+ = \emptyset, \\
b_{12} > 0 \quad &\text{and} \quad \Gamma_1^- = \Omega_1^- = \Gamma_2^- = \Omega_2^- = \emptyset, \\
b_{12} < 0 \quad &\text{and} \quad \Gamma_1^+ = \Omega_1^+ = \Gamma_2^- = \Omega_2^- = \emptyset, \\
b_{12} < 0 \quad &\text{and} \quad \Gamma_1^- = \Omega_1^- = \Gamma_2^+ = \Omega_2^+ = \emptyset.
\end{align*}
\]
Then $d_0 \in C_n \cap \partial D_S$ satisfies (2.12) or (2.13), respectively, under the following assumptions: $E_n$ contains a function which is uniformly positive (bounded away from 0) on $\Omega_1 \cup \Omega_2 \cup \Gamma_1 \cup \Gamma_2$, and at least one of the following holds:
(1) $\Omega_1 = \Gamma_1 = \emptyset$.
(2) $d_0 \notin \bigcup_{m \neq n} C_m$ and there is no nonzero function in $E_n$ which is nonnegative on $\Omega_1 \cup \Gamma_1$ and nonpositive on $\Omega_2 \cup \Gamma_2$.

Proof. The positive function from the hypothesis (or its negative) proves that the first assumption of (2.12) or (2.13) holds, respectively. In case $\Omega_1 = \Gamma_1 = \emptyset$ we have $K_1 = \mathbb{V}$, and otherwise the hypothesis implies $E_n \cap K_1 \cap (-\sigma K_2) = \{0\}$. In both cases, the second assumption in (2.13) or (2.12), respectively, is trivially satisfied.

In order to formulate a slightly more powerful version of our main result, we need yet another notion. We call a point $(\hat{d}_1, \hat{d}_2) \in \mathbb{R}_+^2$ a non-bifurcation point of stationary solutions of (2.11) if there is a neighborhood of $(\hat{d}_1, \hat{d}_2, 0, 0)$ in $\mathbb{R}^2 \times \mathbb{V}^2$ such that every $(d_1, d_2, u, v)$ in this neighborhood satisfying (2.11) (with $u' = v' := 0$) satisfies $u = v = 0$.

Now our main result can be formulated as follows:

**Theorem 1.** Suppose (2.1), (2.3), (2.4), (2.8), and (2.15). Let $d_0 \in \mathbb{R}_+^2 \cap \partial D_S$ be as above, satisfying (2.12) or (2.13). Then the set $D$ of non-bifurcation points of stationary solutions of (2.11) in $D_S$ is open and contains $D_S \cap B_r(d_0)$ for some open ball $B_r(d_0) \subseteq \mathbb{R}_+^2$ around $d_0$; $r > 0$ can even be chosen independent of $g_i$. Let $D_0$ denote the connected component of $D$ which contains $D_S \cap B_r(d_0)$. Then for each $(d_1, d_2) \in D_0$ the trivial solution of system (2.11) fails to be asymptotically stable in the $\mathbb{V}^2$ topology.

We require the condition (2.15) only to simplify the proof and to use a technical result from [2] where this condition was imposed. Actually, Theorem 1 can be shown also without the hypothesis (2.15) if one uses a corresponding variant of the mentioned technical result which will be given in a forthcoming paper.

Our proof of Theorem 1 does not show that the trivial solution is unstable; only the failure of asymptotic stability is claimed. However, our proof will show that the trivial solution fails to be “spherically stable” (which will be defined in Remark 3).

The main difference of Theorem 1 to the corresponding result in [4] is that in the latter, points $(d_1, d_2)$ with large values $d_1, d_2 > 0$ play a crucial role instead of points $(d_1, d_2)$ close to a certain hyperbola $C_n$ (or to $C_n \cap C_m$). This makes a fundamental difference in the hypotheses of the two results: While in [4] there is apparently no
hypothesis similar to (2.12)/(2.13), this hypothesis is implicitly in an requirement about $E_0$ (corresponding to the eigenvalue $\kappa_0 = 0$). In fact, the corresponding result in [4] applies only to the non-Dirichlet case $\Gamma_D = \emptyset$ and only if there is no obstacle for $u$ ($\Omega_1 = \Gamma_1 = \emptyset$) and the obstacle for $v$ acts in a uniform direction ($\Gamma^-_2 = \Omega^-_2 = \emptyset$ or $\Gamma^-_1 = \Omega^-_1 = \emptyset$). It seems likely that none of these additional requirements can be dropped for the result from [4] (since they are crucial for a major tool provided by [5]). In contrast, Theorem 1 needs none of these requirements, but instead (2.12)/(2.13) is needed.

3. The Krasnosel’skii-Quittner formula and instability

In this section, we show a variant of the main result from [4], which in contrast to [4] does not require us to consider artificial scalar products in the spaces for the application.

Let $(V, \langle \cdot, \cdot \rangle, \|\cdot\|)$ and $(H, (\cdot, \cdot), |\cdot|)$ be Hilbert spaces such that there is a compact dense embedding $V \subseteq H$ which we treat notationally as the identity. As is common practice in this setting, we identify notationally also the dual space $H' \sim H$ and work with the adjoint embedding $H' \subseteq V'$ (which just restricts functionals), assuming that the corresponding duality map $(\cdot, \cdot) : V' \times V \rightarrow \mathbb{R}$ is compatible with the scalar product of $H$ and thus using the same symbol. We denote the functional norm in $V'$ induced by this duality map by $\|\cdot\|_{V'}$.

Let $A : V \rightarrow V'$ be a linear isomorphism onto $V'$. Putting $D(A) := A^{-1}(H) \subseteq V \subseteq H$, we let $A := A|_{D(A)} : D(A) \rightarrow H$ denote the $H$-realization of $A$. Suppose that there exist $c_0, c_1 \in [0, \infty)$ with

$$
\langle A^{-1}u, v \rangle \leq c_0 |u||v| \quad \text{for all } u \in H, \ v \in V \subseteq H,
$$

$$
|u|^2 \leq c_1 \langle A^{-1}u, u \rangle \quad \text{for all } u \in V \subseteq H,
$$

$$
\langle A^{-1}u, v \rangle = \langle u, A^{-1}v \rangle \quad \text{for all } u, v \in V \subseteq H.
$$

We consider a closed convex set $K \subseteq V$ with the following property:

$$
((u, \varphi - v) \geq 0 \quad \text{for all } \varphi \in K) \iff ((A^{-1}u, \varphi - v) \geq 0 \quad \text{for all } \varphi \in K) \quad \text{for all } v \in K, u \in V.
$$

Given an open set $\mathcal{U} \subseteq V$ and a map $F : \mathcal{U} \rightarrow H$, we are interested in the variational inequality

$$
u(t) \in K, \quad \left( \frac{du(t)}{dt} + A(u(t)) - F(u(t)), \varphi - u(t) \right) \geq 0 \quad \text{for all } \varphi \in K.
$$
More precisely, we assume that \( \mathcal{U} \) is a neighborhood of a given stationary solution \( u_0 \) of (3.5), that is,

\[
(3.6) \quad u_0 \in K, \quad (\mathcal{A}u_0 - F(u_0), \varphi - u_0) \geq 0 \quad \text{for all } \varphi \in K,
\]

and we require that \( F \) satisfies the Lipschitz/Hölder type conditions

\[
(3.7) \quad |F(u) - F(v)| \leq c_2 \|u - v\|, \quad \|F(u) - F(v)\|_{V'} \leq c_3 |u - v|^\alpha \quad \text{for all } u, v \in \mathcal{U},
\]

where \( \alpha > 0 \) and \( c_2, c_3 \in [0, \infty) \).

For every compact and continuous map \( G: \mathcal{U} \to V \) which has \( u_0 \) as an isolated fixed point, we denote by \( \text{ind}(G, u_0) \) the local fixed point index of \( G \) at \( u_0 \), that is, \( \text{ind}(G, u_0) \) is defined as the Leray-Schauder degree \( \text{deg}(\text{id} - G, \mathcal{U}_0, 0) \) on an open bounded set \( \mathcal{U}_0 \subseteq \mathcal{U} \) containing \( u_0 \) as the only fixed point. The excision property of the Leray-Schauder degree implies that this index is independent of the particular choice of \( \mathcal{U}_0 \).

Similarly, if \( G: \mathcal{U} \cap K \to K \) is compact and continuous and has \( u_0 \) as an isolated fixed point, we define \( \text{ind}_K(G, u_0) \) as the local fixed point index of \( G \) at \( u_0 \) relative to \( K \), that is, as the local fixed point index of the map \( G \circ \varrho \) where \( \varrho \) is a retraction of an open neighborhood \( \mathcal{U}_0 \subseteq \mathcal{U} \) onto \( K \cap \mathcal{U}_1 \) where \( \mathcal{U}_1 \subseteq V \) is an open neighborhood of \( u_0 \). The commutativity and excision property of the fixed point index imply that this value is independent of the choice of \( \varrho \) and \( \mathcal{U}_1 \). In particular, one can choose \( \varrho = P_K \) as the metric projection, that is, \( P_K(u) \) is the unique element of \( K \) of the closest distance (with respect to \( \|\cdot\| \)) to \( u \).

**Theorem 2.** Under the above hypotheses, we find for each initial value \( u_1 \in \mathcal{U} \) a unique weak solution \( \Phi(t)u_1 = u(t) \) of (3.5) satisfying \( u(0) = u_1 \) which exists until \( u(t) \) meets the boundary of \( \mathcal{U} \) (or tends to \( \infty \)). This solution satisfies (3.5) for every such \( t > 0 \) if we interpret \( du(t)/dt \) as the right-sided derivative. For every time \( t > 0 \) the translation-in-time operator \( \Phi(t) \) is compact and continuous on its domain of definition; it is at least defined for small \( t > 0 \). Moreover, if \( \text{ind}(P_K \circ A^{-1} \circ F, u_0) \) is defined then so is \( \text{ind}_K(\Phi(t), u_0) \) for small \( t > 0 \) and has the same value. If this value is defined and differs from 1 then at least one of following two assertions holds:

1. For sequences \( 0 < r_n \to 0 \) and \( t_n > 0 \) there is some \( n \) such that there are \( u \in K \) and \( t > t_n \) such that \( \|u - u_0\| = r_n \) and \( \Phi(t_u)(u) \) is undefined or satisfies \( \|\Phi(t)(u) - u_0\| > r_n \).
2. There is a sequence \( u_n \in K \) with \( 0 < \|u_n - u_0\| \to 0 \) such that \( u_n \) is the initial value of a periodic (non-stationary) solution. In both of these cases, \( u_0 \) fails to be asymptotically stable in the topology of \( V \).
Remark 3. We do not claim in Theorem 2 that $u_0$ fails to be (Ljapunov) stable. However, Theorem 2 implies that $u_0$ lacks the following stability property.

We call $u_0$ spherically stable if $u_0$ has a neighborhood (in $V$) which is free of (initial values of) non-stationary periodic solutions, and if for every $\varepsilon > 0$ there is $t_\varepsilon > 0$ such that every $u \in K$ with $\|u - u_0\| = \varepsilon$ satisfies $\|\Phi(t)(u) - u_0\| \leq \varepsilon$ for all $t > t_\varepsilon$.

The latter is neither stronger nor weaker than the classical notion of (Ljapunov) stability: It is stronger in the sense that the same $\varepsilon > 0$ occurs twice, but it is weaker in the sense that there is no requirement for $t \leq t_\varepsilon$, i.e., the trajectories may go arbitrarily far away from $u_0$ if they only return close enough to $u_0$ in time.

Proof. We replace first $(\cdot, \cdot)_{V' \times V}$ by

$$(u, v)^* := \langle \mathfrak{A}^{-1}u, v \rangle$$

for all $u \in V'$ and $v \in V$.

The associated functional norm $\|\cdot\|^*$ in $V'$ satisfies

$$\|u\|^* := \sup_{\|v\| \leq 1} |(u, v)^*| = \|\mathfrak{A}^{-1}u\|$$

and thus is equivalent to $\|\cdot\|_{V'}$ since $\mathfrak{A} : V \to V'$ is an isomorphism. For $u \in H$, we have by (3.1) that

$$(3.8) \quad (u, v)^* \leq c_0 |u||v| \quad \text{for all } v \in V,$$

and so $(u, \cdot)^*$ is Lipschitz on $V \subseteq H$ with respect to $|\cdot|$ with Lipschitz constant $c_0 |u|$ and thus has a unique continuous extension to $H$ with the same Lipschitz constant, which we denote again by $(u, \cdot)^*$. It follows that such extended bilinear form $(\cdot, \cdot)^*$ is continuous on $H \times H$. From (3.3) we obtain that $(\cdot, \cdot)^*$ is symmetric on $V \times V$ and thus by continuity and density also on $H \times H$. By (3.2), we have

$$c_1(u, u)^* = c_1 \langle \mathfrak{A}^{-1}u, u \rangle \geq (u, u)$$

for all $u \in V$, and from density and continuity, we obtain that $(\cdot, \cdot)^*$ is positive definite and thus an inner product on $H$ inducing a norm $|\cdot|^*$ satisfying $\sqrt{c_1}|u|^* \geq |u|$. In view of (3.8), we conclude that the two scalar products on $H$ are actually equivalent. Note now that none of the assertions or hypotheses of the theorem changes when we replace $(\cdot, \cdot)$ by $(\cdot, \cdot)^*$: Indeed, (3.4) implies

$$((u, \varphi - v) \geq 0 \quad \text{for all } \varphi \in K) \iff ((u, \varphi - v)^* \geq 0 \quad \text{for all } \varphi \in K)$$

also for all $u \in H$ by the density of $V$ and by continuity of the scalar product. Hence, even (3.5) does not change when we replace $(\cdot, \cdot)$ by $(\cdot, \cdot)^*$. Thus, we can assume without loss of generality that $(\cdot, \cdot) = (\cdot, \cdot)^*$. In this case, $(\mathfrak{A}u, v) = (\mathfrak{A}u, v)^* = (u, v)$, that is, the operator $\mathfrak{A}$ has the particular form required in [4], and so the assertion follows from the main theorem of [4] and the remarks given there. \qed
Theorem 2 becomes in case \((u, v) = \langle A^{-1}u, v \rangle\) exactly a reformulation of [4]. However, the above formulation is more handy since it allows us to put parameters into the operator \(\mathfrak{A}\) instead of the scalar products which caused technical inconveniences in [4]. The apparently restrictive hypothesis (3.4) is actually trivially satisfied for convex sets of the form \(K = K_1 \times K_2\) in the setting which we describe now.

4. Proof of Theorem 1

The first step consists of rewriting (2.11) equivalently in the form (3.5) by defining \(H, V, \mathfrak{A}\), and \(F\) appropriately.

It will simplify our considerations to equip \(V\) with the scalar product

\[
\langle u, \varphi \rangle := \int_{\Omega} \nabla u \cdot \nabla \varphi \, dx \quad \text{for all } u, \varphi \in V
\]

which in view of (2.15) generates the topology inherited from \(W^{1,2}(\Omega)\), see e.g. [10].

We denote the usual scalar product in \(L^2(\Omega)\) by \((\cdot, \cdot)\). Our aim is to apply Theorem 2 in the Hilbert spaces \(V = \mathbb{V} \times \mathbb{V}\) and \(U = L^2(\Omega) \times L^2(\Omega)\) with the sum scalar products, that is (using in a slight misuse of notation the symbols for the scalar product in a duplicate meaning), we put

\[
\left( \begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} \varphi \\ \psi \end{pmatrix} \right) = \langle u, \varphi \rangle + \langle v, \psi \rangle = \int_{\Omega} (\nabla u \cdot \nabla \varphi + \nabla v \cdot \nabla \psi) \, dx,
\]

\[
\left( \begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} \varphi \\ \psi \end{pmatrix} \right) = (u, \varphi) + (v, \psi) = \int_{\Omega} (u \varphi + v \psi) \, dx.
\]

We define a linear \(A_0: L^2(\Omega) \to \mathbb{V}\) by the duality

\[
\langle A_0 u, \varphi \rangle = (u, \varphi) = \int_{\Omega} u \varphi \, dx \quad \text{for all } u \in L^2(\Omega), \varphi \in \mathbb{V}.
\]

For fixed \(d_1, d_2 > 0\), we define \(\mathfrak{A}: V \to V'\) by

\[
\mathfrak{A} \begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} \varphi \\ \psi \end{pmatrix} = \int_{\Omega} (d_1 \nabla u \cdot \nabla \varphi + d_2 \nabla v \cdot \nabla \psi) \, dx.
\]

Since the right-hand side is (up to an equivalence) the scalar product in \(V\), it is clear that \(\mathfrak{A}: V \to V'\) is an isomorphism. Letting \(A := \mathfrak{A}|_{\mathfrak{A}^{-1}(H)}\) we have \(A^{-1} = \mathfrak{A}^{-1}|_H\),

\[
A^{-1} \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} d_1^{-1} A_0 u \\ d_2^{-1} A_0 v \end{pmatrix} \quad \text{for all } \begin{pmatrix} u \\ v \end{pmatrix} \in H,
\]

207
or in other words
\[
\left\langle A^{-1}\begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} \varphi \\ \psi \end{pmatrix} \right\rangle = d_1^{-1}(u, \varphi) + d_2^{-1}(v, \psi) \quad \text{for all } \begin{pmatrix} u \\ v \end{pmatrix} \in H, \begin{pmatrix} \varphi \\ \psi \end{pmatrix} \in V.
\]

From this representation it follows immediately that (3.1), (3.2), and (3.3) are satisfied for every \(d_1, d_2 > 0\).

Moreover, putting \(K := K_1 \times K_2\), we have (3.4). Indeed, with the notation 
\(u = (u_1, u_2), \ v = (v_1, v_2)\) the particular choices \(\varphi \in K_1 \times \{v_2\}\) and \(\varphi \in \{v_1\} \times K_2\) show that actually both statements in (3.4) are equivalent to
\[(u_i, \varphi_i - v_i) \geq 0 \quad \text{for all } \varphi_i \in K_i \text{ and } i = 1, 2.\]

For \(i = 1, 2\), we define \(F_i, G_i : V \to L_2(\Omega)\) as the superposition operators
\[F_i(u, v)(x) = f_i(u(x), v(x)), \quad G_i(u, v)(x) = g_i(u(x), v(x)).\]

In view of Sobolev's embedding theorems it follows straightforwardly from our hypothesis (2.4) that these operators are indeed well-defined and satisfy a Lipschitz condition on some neighborhood \(\mathcal{U} \subseteq V\) of \(u_0 := 0\); see e.g. [4] for an analogous calculation. Hence, putting \(F := (F_1, F_2) : \mathcal{U} \to H\), we obtain that the Lipschitz condition in (3.7) is satisfied, and a calculation analogous to that given in [4] shows that also the Hölder condition in (3.7) is satisfied if \(\mathcal{U} \subseteq V\) is bounded (and small enough in case \(N = 1\)).

Now we prove the assertions of Theorem 1: The fact that the set \(D\) of non-bifurcation points is open, follows immediately from the definition. In [2], Lemma 3.4, it has been proved that for every \(d_0 \in \mathbb{R}_+^2 \cap \partial D_S\) satisfying (2.12) or (2.13), there is \(r > 0\) such that the open ball \(B_r(d_0) \subseteq \mathbb{R}_+^2\) has the property that \(B_r(d_0) \cap D_S\) is free of so-called critical points, in particular, it consists only of non-bifurcation points (independent of the particular higher-order term \(g_i\)). Observe that (4.1) implies
\[(A^{-1} \circ F) \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} d_1^{-1}b_{11}A_0u + d_1^{-1}b_{12}A_0v \\ d_2^{-1}b_{21}A_0u + d_2^{-1}b_{22}A_0v \end{pmatrix} + \begin{pmatrix} d_1^{-1}A_0G_1(u, v) \\ d_2^{-1}A_0G_2(u, v) \end{pmatrix}.
\]

This is exactly the operator which occurs in [2] (the second summand is called \(F\) in [2]), and [2], Theorem 3.1, thus implies that
\[(4.2) \quad \text{ind}(P_K \circ A^{-1} \circ F, 0) = 0\]

for \((d_1, d_2) \in D_S \cap B_r(d_0)\). Note that the homotopy invariance of the degree implies that the local fixed point index \(\text{ind}(P_K \circ A^{-1} \circ F, 0)\) is a locally constant function of \((d_1, d_2) \in D\). Hence, this index is constant on the connected components of \(D\), and so (4.2) holds for all \((d_1, d_2) \in D_S\). Now the assertion about the instability follows from Theorem 2. \qed

208
5. Proof of Proposition 1

We consider almost the same setting as in Section 4, but in order to include \( \Gamma_D = \emptyset \), we have to equip \( \mathbb{V} \) with the usual scalar product

\[
\langle u, v \rangle := (u, v) + \langle \nabla u, \nabla v \rangle.
\]

We use the same formulas as in Section 4 to define \( A_0, A, F, \) and \( G \), observing that the definitions of \( A, A, F, \) and \( G \) do not involve the scalar product of \( \mathbb{V} \) at all. In particular, \( F: \mathbb{V} \to H \) is locally Lipschitz near 0 by the same arguments as before. Note that (2.4) implies for \( N \geq 2 \) that

\[
|f_i(u, v)| \leq C(1 + |u| + |v|)^{\alpha N + 1}.
\]

By the Sobolev embedding theorems (see e.g. [10]), the space \( W^{1,2}(\Omega) \) is continuously embedded into \( C(\Omega) \) (in case \( N = 1 \)) or into \( L^q(\Omega) \) with \( q/2 = \alpha N + 1 \) (in case \( N \geq 2 \)). (Indeed, in case \( N \geq 3 \) the critical Sobolev exponent is \( q := 2N/(N-2) = 2(\alpha N + 1) \).

Thus, we obtain from (2.3) and (5.1) (using e.g. [9], Theorem 4.16, in case \( N \geq 2 \)) that

\[
\lim_{\| (u, v) \| \to 0} \frac{\| G(u, v) \|}{\| (u, v) \|} = 0.
\]

Hence, everything is prepared to apply [3], Theorem 5.1.1, in the space \( X := H \) with our operator \( A: D(A) \to X \), the corresponding fractional power space \( X^{1/2} = V \), and with our nonlinearity \( F \) whose linearization is

\[
B_0(u, v) := F(u, v) - G(u, v) = \begin{pmatrix} b_{11} u & b_{12} v \\ b_{21} u & b_{22} v \end{pmatrix}
\]

(in [3], Theorem 5.1.1, this map is called \( B \)). It remains to show that for \( (d_1, d_2) \in D_S \) the real parts of the spectrum of \( A - B_0 \) are bounded by some \( \gamma < 0 \), that is, that for all \( \lambda \in \mathbb{C} \) with \( \text{Re} \lambda \geq \gamma \) the operator \( C_\lambda := A - B_0 - \lambda \text{id} \) has a bounded inverse in \( H \). Putting \( A_1 := A_0^{-1} - \text{id}: \mathbb{V} \to L^2(\Omega) \), we can rewrite \( C_\lambda(u, v) = (f, g) \) as the system

\[
\begin{align*}
d_1 A_1 u - (b_{11} - \lambda) u + b_{12} v &= f, \\
b_2 A_1 v - b_{21} u - (b_{22} - \lambda) v &= g.
\end{align*}
\]

Note that \( A_1 \) is a self-adjoint operator in \( L^2(\Omega) \) with spectrum \( \sigma(A_1) \) consisting exactly of the values \( \kappa_n > 0 \) \((n = 1, 2, \ldots)\) and in case \( \text{mes} \Gamma_D = 0 \) also of \( \kappa_0 := 0 \). For \( \lambda \notin (\infty, b_{22}] \), we can thus calculate \( C_\lambda^{-1} \) “explicitly” by first solving the second
equation in (5.2) for $v$ and then inserting into the first equation. We do this in terms of spectral calculus: Defining $h: \sigma(A_1) \to \mathbb{C}$ by

$$h(\kappa) := d_1\kappa - (b_{11} - \lambda) - b_{12} \frac{-b_{21}}{d_2\kappa - (b_{22} - \lambda)};$$

we have to show that $h(A_1)$ has a bounded inverse (for $\text{Re}\lambda \geq \gamma$), that is, by the spectral mapping theorem, that $0 \notin h(\sigma(A)) = h(\sigma(A))$ (the closure can be omitted since $|h(\kappa_n)| \to \infty$ as $n \to \infty$.)

Let $\Lambda$ denote the set of all $\lambda \in \mathbb{C} \setminus (-\infty, b_{22}]$ with $0 \in h(\sigma(A))$. Multiplying by the nominator (for which we already verified that it is nonzero), we find that $\lambda \in \Lambda$ implies that there is some $n = 0, 1, \ldots$ with

$$(d_1\kappa_n - b_{11} + \lambda)(d_2\kappa_n - b_{22} + \lambda) = b_{12}b_{21}. \quad (5.3)$$

For each $n$, we thus have at most two values $\lambda_{n,1}, \lambda_{n,2}$ in $\Lambda$ which are exactly the eigenvalues of the matrix

$$B + \kappa_n \begin{pmatrix} -d_1 & 0 \\ 0 & -d_2 \end{pmatrix}.$$

Dividing this matrix by $\kappa_n \to \infty$, we can assume that (after an appropriate ordering) $\kappa_n^{-1}\lambda_{n,j} \to -d_j < 0$ so that the set of all real parts of elements of $\Lambda$ has a maximum $\gamma$. We fix some $n$ with $\max_j \text{Re}\lambda_{n,j} = \gamma$. Using the shortcuts $\alpha_n := d_1\kappa_n - b_{11}$ and $\beta_n := d_2\kappa_n - b_{22}$, we find by Vieta’s theorem from (5.3) that

$$(5.4) \quad \lambda_{n,1} + \lambda_{n,2} = -(\alpha_n + \beta_n) \leq b_{11} + b_{22} < 0,$$

$$\lambda_{n,1}\lambda_{n,2} = \alpha_n\beta_n - b_{12}b_{21} > 0,$$

where the last inequality follows in case $n = 0$ from (2.1) and in case $n \geq 1$ from the assumption $(d_1, d_2) \in D_S$. Note that $\lambda_{n,1}, \lambda_{n,2}$ are either both real or conjugate complex. In both cases, we obtain from (5.4) that $\text{Re}\lambda_{n,j} < 0$, and so $\gamma < 0$. Hence, the real parts of the elements of $\Lambda$ are all bounded from above by $\gamma < 0$. By construction, $\Lambda \cup (-\infty, b_{22}]$ contains the spectrum of $A - B_0$, and so we are done. \qed
